Psychological distress and suicidal behaviours in Indigenous and non-Indigenous adults living off-reserve in Canada: What explains the differences?

ABSTRACT

BACKGROUND: Indigenous peoples are disproportionately affected by mental health issues in Canada. We investigated factors underlying the difference in psychological distress and suicidal behaviours between Indigenous peoples living off-reserve in Canada and the non-Indigenous population.

METHODS: Using data from the 2012 Canadian Community Health Survey – Mental Health we measured the variation in psychological distress (10-item Kessler Psychological Distress Scale [K10] scores, ranging from 10 [no distress] to 50 [severe distress]) and the prevalence of lifetime suicidal ideation and suicide plan between the two populations and explained these differences using the Blinder–Oaxaca approach.

RESULTS: Among 18,300 representing 18,573,280 adults (aged ≥ 18 yr), we found higher mean scores of psychological distress among Indigenous peoples compared to the non-Indigenous population (16.04 v. 15.05, $P < 0.001$), and a higher prevalence of lifetime suicidal ideation (9.2% v. 16.8%, $P < 0.001$) and plan (2.3% v. 6.8%, $P < 0.001$). Results indicated that 60% (women: 51.2%; men: 78.3%) of the variation in psychological distress was explained by the differences in demographic, socioeconomic and geographical factors between the two populations. The group differences in response to the characteristics and unobserved characteristics mainly explained the differences in suicidal behaviours. We found if socioeconomic status in Indigenous peoples were made to be similar to non-Indigenous population, the differences in mean distress scores, prevalence of lifetime suicide ideation and plan would have been reduced by 25.7% (women: 20.8%; men 36.9%), 10.2% (women: 11.2%; men 11.9%) and 5.8% (women: 7.8%; men 8.1%), respectively.

INTERPRETATION: Improving socioeconomic covariates among Indigenous peoples through plans like income equalisation may reduce the gap in mental health outcomes between Indigenous and non-Indigenous populations in Canada.

1
2
3 The historical, political and socioeconomic factors that uniquely affect Indigenous peoples
4 have resulted in poorer health outcomes compared to non-Indigenous people in Canada.¹⁻⁸ Of
5 particular concern is the disproportionate burden of mental health issues among Indigenous
6 peoples.⁹⁻¹¹ A growing number of studies reveal the extent of inequality in physical health
7 and mental health between Indigenous and non-Indigenous populations.^{4,12-14} For example,
8 just under one-quarter of Inuit (23.5%) and First Nations adults living off-reserve (24.0%),
9 and one in five Métis (19.6%) reported lifetime suicidal ideation, compared to just over one in
10 ten among non-Indigenous adults.¹⁵ Furthermore, a recent study¹⁶ published in this journal
11 uncovers inequalities in mental health outcomes *within* Indigenous peoples in Canada.
12
13

14
15 To assist effective policy making based on the emerging evidence of the extent of inequalities,
16 it is critical to understand what explains these inequalities. Recent studies^{16,17} highlighted
17 the importance of social determinants of health in inequalities in health and mental health
18 outcomes *within* Indigenous peoples in Canada. These studies show, for example, policies
19 designed to address food insecurity may help reduce mental health issues among Indigenous
20 peoples living off-reserve in Canada. Extending the increasing efforts to document and
21 understand health inequalities faced by Indigenous populations, this study aims to explain
22 inequalities in mental health outcomes *between* Indigenous peoples and the non-Indigenous
23 population in Canada. We used data from the 2012 Canadian Community Health Survey –
24 Mental Health (CCHS–MH) to quantify the extent and explain various demographic,
25 socioeconomic and geographical factors that account for inequalities in psychological distress,
26 suicidal ideation, and suicide plans *between* Indigenous peoples living off-reserve in Canada
27 and non-Indigenous Canadians.

42 43 *Sample*

44
45 Data for the study derived from the 2012 CCHS–MH. This cross-sectional survey collected
46 information on major mental health status and the provision of mental health care services
47 from the Canadian population. The survey is a large nationally representative survey of
48 individuals aged ≥ 15 yr living in the ten provinces in Canada, except those living on reserves
49 and other Indigenous settlements, full-time members of the Canadian Forces, and the
50 institutionalized population. These exclusions approximately represent 3% of the target
51 population. The response rate of the survey was 68.9%.¹⁸

Variables

The outcome variables included psychological distress, lifetime suicide ideation and lifetime suicide plan. The 10-item Kessler Psychological Distress Scale (K10, see Appendix A)¹⁹ was used to identify psychological distress of individuals. The K10 is comprised of items evaluating psychological and physiological symptoms of depression and anxiety. The overall K10 scores range from 10 (no distress) to 50 (severe distress). The K10 is shown to be appropriate and valid for use in Indigenous populations living on and off-reserve in Canada.^{19–22} Based on the information available in the CCHS–MH, we constructed two binary variables (yes or no) assessing lifetime suicidal ideation and suicide plan. Indigenous populations in this study refers to all Inuit, Métis and First Nations peoples living off-reserve in Canada. As per the existing literature^{16,17,23–31} and availability of questions assessed in the CCHS–MH, we considered a variety of demographics (sex, age and marital status), socioeconomic (equivalized household income, education, employment status, household arrangement and homeownership status) and geographic (urbanicity and region) variables known to be associated with mental health outcomes. We equivalized annual household income by dividing it by the square root of household size.³² Appendix B presents the definitions and descriptive statistics of all the variables used in the study.

Statistical Analysis

We first performed the ordinary least squares (OLS) and non-linear logit regressions to investigate the effect of determinants on the continuous psychological distress, and two binary suicidal behaviours, respectively. Subsequently, we used the Blinder-Oaxaca (BO) decomposition method^{33,34} to understand the contribution of each factor to the overall differences in the three mental health outcomes between non-Indigenous and Indigenous peoples. The BO technique enabled us to decompose the observed gaps between Indigenous and non-Indigenous peoples into explained and unexplained components. The explained (endowment) component captures the part of the difference in a given outcome explained by differences between groups in the level of observed characteristics (determinants) that were assessed (i.e., demographic, socioeconomic and geographic variables). The unexplained component captures the portion attributable to differences in the effects (response or return) of these characteristics and unobserved determinants on the outcome of interest in non-Indigenous and Indigenous population. The absolute value of the explained component for income factor, for example, can determine how much the gap in the mean of psychological

1
2
3 distress levels between non-Indigenous and Indigenous populations would have been reduced
4 if the income of Indigenous peoples is set to be at the similar level of non-Indigenous
5 Canadian, *ceteris paribus*.^{33–35} We used the BO decomposition for a linear model to assess the
6 differences in the mean psychological distress. An extended version of the BO technique for
7 a non-linear logit model³⁵ was used to examine the difference in the prevalence of suicidal
8 ideation and suicide plans. Appendix C provides a detailed description of our regression and
9 decomposition analyses.

10
11 To acknowledge potential differential results by sex, we stratified all analyses by sex. The t-
12 test and chi-square statistics were used to test the differences in continuous (i.e.,
13 psychological distress) and categorical (i.e., suicidal ideation and lifetime suicide plan)
14 variables between non-Indigenous and Indigenous populations, respectively. We considered
15 $p < 0.05$ as statistically significant. As per Statistics Canada's Research Data Centre
16 guidelines, all analyses were weighted to represent all adults living off-reserve in Canada.
17 We performed all the analyses in Stata 14.³⁶

25 **Results**

26 ***Sample characteristics***

27
28 The CCHS–MH contains information of 25,113 participants.¹⁸ After we excluded individuals
29 aged < 18 yr and individuals with missing values in outcomes or explanatory variables, our
30 final sample consisted of 18,300 (Indigenous: 933 and non-Indigenous: 17,367) individuals,
31 representing 18,573,280 (Indigenous: 754,982 and non-Indigenous: 17,818,298) individuals
32 in Canada. The mean scores of psychological distress was higher in Indigenous compared to
33 non-Indigenous populations (total: 16.04 v. 15.05, $P < 0.001$; women: 16.53 v. 15.32, $P = 0.007$;
34 men: 15.59 v. 14.78, $P = 0.03$). The prevalence of lifetime suicidal ideation (total: 16.80% v.
35 9.20%, $P < 0.001$; women: 19.10% v. 9.69%, $P < 0.001$; men: 14.60% v. 8.70%, $P = 0.005$) and

lifetime suicide plan (total: 6.81% v. 2.23%, $P < 0.001$; women: 7.73% v. 2.66%, $P = 0.008$; men: 5.94% v. 1.98%, $P = 0.006$) among Indigenous population was found to be higher than non-Indigenous Canadians (Table 1).

<<< Insert Table 1 here >>>

The Indigenous population in Canada was younger than in the non-Indigenous population. It is apparent that equivalised household annual income of Indigenous peoples (total: C\$46,550; women: C\$44,482; men: C\$48,488) was less than non-Indigenous population (total: C\$54,426; women: C\$52,076; men: C\$56,846). The educational level gap exists between the two groups with Indigenous peoples having lower educational attainment compared to their non-Indigenous population. While 61.9% (women: 55.9%; men: 68.2%) of non-Indigenous men were employed in Canada, this figure was 57.6% (women: 56.1%; men: 58.9%) in Indigenous population. The proportion of homeownership was higher in non-Indigenous as compared to Indigenous peoples living in Canada.

Determinants of psychological distress and suicidal behaviours

There were negative associations between age and mental health outcomes in both women and men. A one-year increase in age was associated with a decreased of 0.054 (women: 0.068; men: 0.043) points in distress score and 0.11 (women: 0.12; men: 0.09) percentage points in the probability of having lifetime suicide ideation. The probability of lifetime suicide plan also decreases by age among men. Higher-income level was a protective factor against all the three mental health outcomes in women and men. Psychological distress among employed individuals was lower compared to those unemployed and those with other employment status. Home ownership associated negatively with distress levels and lifetime suicide ideation. Compared to Ontario female residents, distress was found to be lower among the female residents of Quebec. Individuals residing in Prairie had higher probabilities of reporting lifetime suicide ideation. The probability of lifetime suicide plan was higher among men living in Quebec and Prairie provinces. After controlling for the difference in the observable factors, there was not statistically significant difference in distress level between the Indigenous and non-Indigenous populations. However, Indigenous peoples had higher probability of reporting lifetime suicide ideation and lifetime suicide plan after adjusting for the observable characteristics.

<<< Insert Table 2 here >>>

Explaining differences in psychological distress and suicidal behaviours

The mean score of the psychological distress for non-Indigenous population in Canada was found to be 0.992 (women: 1.208; men 0.814) points lower than their Indigenous counterparts. The BO decomposition results suggested the difference in the characteristics between the two groups explains 60% (women: 51.2%; men: 78.3%) of the difference in the mean score of psychological distress. Differential distribution of factors including age, household income, and homeownership between non-Indigenous and Indigenous population, has accounted for the higher mean score of psychological distress among Indigenous population. For example, if the Indigenous population had the same equalized household income as their non-Indigenous counterparts, the difference in the mean score of psychological distress could potentially decrease by 0.132 (women: 0.132; men: 0.133) points, *ceteris paribus* (Table 3 and Figure 1).

<<< Insert Table 3 and Figure 1 here>>>

The prevalence of lifetime suicide ideation for non-Indigenous in Canada was 7.57 (women: 9.39; men: 5.90) percentage points lower than their Indigenous counterparts. The decomposition results suggested that difference in the characteristics explained 23.5% (women: 22.5%; men 25.2%) of the difference in the prevalence of lifetime suicide ideation. The differential distribution of factors such as age, income and homeownership between the two groups contributed significantly to the difference in the prevalence of lifetime suicide ideation between Indigenous and non-Indigenous population. The difference in income and homeownership between the two groups explained 0.36 (women: 0.56; men: 0.22) and 0.25 (women: 0.27; men: 0.26) percentage points of the difference in the prevalence of lifetime suicide ideation, respectively (Table 2 and Figure 1). The prevalence of lifetime suicide plan for the non-Indigenous population in Canada was 4.48 (women: 5.07; men 3.96) percentage points lower than the Indigenous population in Canada. The decomposition results suggested statistically marginally significant contribution of explained components to the overall difference in the prevalence of lifetime suicide plan between Indigenous and non-Indigenous populations and between Indigenous and non-Indigenous men. If Indigenous people had the same observed characteristics as their non-Indigenous population in Canada, the difference in the prevalence of lifetime suicide would have been reduced by 9.8% (men:17.0 %). The differential distribution of factors in income between Indigenous and non-Indigenous peoples also contributed to the overall difference in the prevalence of lifetime suicide plan between

1
2
3 the two groups (Table 3 and Figure 1). The sizable contribution of the unexplained component
4 to the overall gaps in suicide behaviours indicates that there are characteristics other than
5 the variables in our model that affect suicide behaviours but that we are unable to observe
6 or control.
7
8
9

10 **Interpretation**

11
12 Health inequalities between Indigenous and non-Indigenous populations continue to exist in
13 Canada, despite calls to action to address these gaps.³⁷ One particularly concerning issue is
14 the substantial differences in certain mental health outcomes between Indigenous and non-
15 Indigenous peoples in Canada^{38,39}, which were observed in the current analyses of the 2012
16 CCHS–Mental Health Survey. Similar to our previous study using data from the 2012
17 Aboriginal Peoples Survey,¹⁶ we showed a high prevalence of psychological distress and
18 suicidal behaviours among Indigenous peoples living off-reserve in Canada. We found that
19 mean psychological distress scores among Indigenous peoples was 6.59% higher compared to
20 the non-Indigenous population. The prevalence of lifetime suicidal ideation (suicide plan)
21 among Indigenous peoples was also found to be 1.61 (3) times higher than the corresponding
22 figures for the non-Indigenous population.
23
24
25
26
27
28
29
30

31 Results indicated that the difference in the mean levels of psychological distress between
32 Indigenous and non-Indigenous was mostly explained by the differences between groups in
33 levels of the explanatory variables that were assessed, particularly for men. The differences
34 in demographic factors accounted for a significant proportion of the differences in distress
35 between Indigenous and the non-Indigenous. In particular, age differences between
36 Indigenous and non-Indigenous adults accounts for one third of the overall gap in distress
37 between the two groups. Age contributed to the differences in distress levels between the two
38 groups because distress decreased with increasing age and Indigenous peoples are younger
39 than non-Indigenous Canadian; thus, distress levels of Indigenous peoples would be less if
40 Indigenous peoples had same age characteristics as non-Indigenous population.
41 Socioeconomic factors also accounted for a quarter of the difference in distress levels between
42 the two groups. Improving socioeconomic status of Indigenous peoples through plans like
43 income equalisation may decrease the gap in psychological distress between Indigenous and
44 non-Indigenous populations in Canada, particularly for men.

1
2
3 Unlike results for psychological distress, results for suicidal behaviours showed that the gaps
4 in suicide behaviours between Indigenous and non-Indigenous populations largely come from
5 differences in the effects of the characteristics and unobserved determinants. Still, our
6 findings underscore the importance of role of socioeconomic factors in accounting for
7 differences in the prevalence of lifetime suicidal ideation and suicide plan. For example,
8 improving the income of Indigenous peoples to the level of the non-Indigenous population
9 could potentially reduce the prevalence of suicidal ideation by 0.25 (i.e., 1,887 cases in our
10 sample of 754,982) percentage points and suicide plan by 0.11 (i.e., 830 cases in our sample
11 of 754,982) percentage points among Indigenous peoples.
12
13
14
15
16
17

18 **Limitations**

19
20
21 Our study is subject to at least five limitations. First, the CCHS–MH does not collect
22 information from individuals living in institutions (e.g., hospitals, prisons) and other
23 collective dwellings (e.g., shelters and group homes) in which there are a disproportionate
24 number of Indigenous peoples who might be expected to have particularly high levels of
25 psychological distress. Restriction of the survey to persons living in private dwellings omits
26 many Indigenous peoples with high-risk of mental health issues.^{40,41} Second, due to the
27 unavailability in the CCHS–MH, we could not assess the impact of some determinants of
28 mental health outcomes such as food insecurity, the long-term effects of residential schools
29 and the child welfare system, and numerous additional cultural, historical and contemporary
30 factors that are known to be important determinants of mental health outcomes specifically
31 among Indigenous peoples. Third, some of the explanatory factors included in the analysis
32 are likely to be endogenous, thus, may result in unknown bias into the findings. For example,
33 we cannot distinguish whether being unemployed lead to a mental health issue and/or mental
34 health issues results in unemployment. Fourth, we could not consider those who have died
35 by suicide in our study, also disproportionately represented among Indigenous populations.¹³
36 Fifth, we combined the three Indigenous populations to ensure a large enough number of
37 Indigenous respondents for the analyses. Since there exist differences in mental health
38 outcomes between and within the three Indigenous groups in Canada¹⁶, further studies are
39 required to examine the differences between non-Indigenous and specific Indigenous
40 populations, separately.

52
53

54 **Conclusion**

High prevalence of psychological distress and suicide facing Indigenous peoples is considered a health priority in Canada. A consensus is that the solution must lie in holistic interventions that go beyond mainstream mental health care services and psychiatric medication^{38,42,43} and address the social determinants of health.^{42,43} Our study suggested that policies designed to improve major contributing socioeconomic determinant of health such as income may help reduce inequalities in mental health outcomes between Indigenous and non-Indigenous populations. The importance of focusing on the social determinants beyond mental health services is well recognized by First Nations, Inuit and Métis peoples and in the current literature in Canada,^{44,45} where psychological distress and suicide are a grave public health concern over the past three decades despite increasing access to mental health care and use of psychiatric medications.

† Negative (positive) value for each characteristic indicates the absolute value of the difference that could have been reduced (increased) if that characteristic for Indigenous peoples were made to be identical to the non-Indigenous population. For example, if the annual equivalized income for Indigenous adults increased to the level of non-Indigenous population, the difference in the psychological distress scale between the two groups could have been decreased by 0.1320 points.

Figure 1: Percentage point contribution of explained and unexplained component to the differences in psychological distress scale and the prevalence of lifetime suicidal ideation and suicide plan between Indigenous peoples living off-reserve in Canada and the non-Indigenous population

Note: Percentage point contributions of explained component were calculated by dividing the sum of the contribution of all variables in each category by the total difference in the corresponding mental health outcome.

Appendix B: The definition variables used in the study

Variables	Description
<i>Outcome Variables</i>	
Psychological distress scale	The Kessler Psychological Distress Scale (K10) score: continuous variable ranging between 10 and 50
Lifetime suicide ideation	1 = if the individual ever considered suicide in the lifetime, 0 otherwise
Lifetime suicide plan	1 = if the individual ever planned suicide in the lifetime, 0 otherwise
<i>Demographic Variables</i>	
Indigenous Identity	
Indigenous	1 = if the individual is self-identified as an Indigenous person, 0 otherwise
Non-Indigenous	1 = if the individual is self-identified as a non-Indigenous person, 0 otherwise
Sex	
Male	1 = if the individual is male, 0 otherwise
Female	1 = if the individual is female, 0 otherwise
Age	
Age of the individual in years	
Marital Status	
Married or <i>de facto</i> married	1 = if the individual is married or de facto married, 0 otherwise
Divorced or widowed	1 = if the individual is divorced or widowed, 0 otherwise
Single	1 = if the individual is single, 0 otherwise
<i>Socioeconomic Variables</i>	
Equivalized Household Income	
Household income divided by the square root of household size	
Education	
Less than high school	1 = if the individual has less than secondary education, 0 otherwise
High school	1 = if the individual has secondary education, 0 otherwise
Some post-secondary	1 = if the individual has some post-secondary education, 0 otherwise
Bachelor's degree or higher	1 = if the individual has post-secondary degree/diploma, 0 otherwise
Employment Status	
Employed	1 = if the individual is employed, 0 otherwise
Unemployed	1 = if the individual is unemployed, 0 otherwise
Other employment status	1 = if the individual is not in labour force or unable to work, 0 otherwise
Homeownership	
Owner	1 = if the individual owns the dwelling, 0 otherwise

Renter	1 = if the individual rents the dwelling, 0 otherwise
Household Arrangement	
Single person	1 = if the household composition is single person, 0 otherwise
Couple with no child	1 = if the household composition is couple with no child, 0 otherwise
Couple with child(ren) younger than 25	1 = if the household composition is couple with a child(ren) less than 25, 0 otherwise
Separate with Child younger than 25	1 = if the household composition is separate with child(ren) less than 25, 0 otherwise
Other household compositions	1 = if the household composition is other, 0 otherwise
<i>Geographical Factors</i>	
Urbanicity	
Urban	1 = if the individual resides in an urban area, 0 otherwise
Rural	1 = if the individual resides in a rural area, 0 otherwise
Geographic Region	
Atlantic (AT)	1 = if the individual resides in Newfoundland and Labrador (NL), Prince Edward Island (PEI), Nova Scotia (NS) and New Brunswick (NB), 0 otherwise
Quebec (QC)	1 = if the individual resides in QC, 0 otherwise
Ontario (ON)	1 = if the individual resides in ON, 0 otherwise
Prairie (PR)	1 = if the individual resides in Manitoba (MB), Saskatchewan (SK), and Alberta (AB), 0 otherwise
British Columbia (BC)	1 = if the individual resides in BC, 0 otherwise

Appendix C: Detailed Statistical Analysis

Regression Analysis

We first performed regression analyses to examine the determinants of the three main mental health outcomes, including psychological distress scale, lifetime suicidal ideation and lifetime suicide plan. We assessed the differences in psychological distress and suicidal behaviour between Indigenous populations living off-reserve and non-Indigenous population in Canada using the following equation:

$$Y_i = \alpha_0 + \alpha_1 \text{Indigenous}_i + \beta X_i + \mu_i. \quad (1)$$

In Equation 1, Y_i denotes the outcome variable for person i , α_0 is the intercept, α_1 is the coefficient on the dummy variable for Indigenous people, X_i is a vector of other control variables (demographic, socioeconomic and geographic factors) and μ_i is the error term. We performed the ordinary least squares (OLS) and non-linear logit models to investigate the effect of determinants on the continuous psychological distress, and two binary suicidal behaviours, respectively.

The Blinder–Oaxaca Decomposition

We employed the Blinder-Oaxaca (BO) decomposition method (1,2) to understand the contribution of each factor to the overall differences in the three mental health outcomes between non-Indigenous and Indigenous peoples. The BO technique enabled us to decompose the observed gaps between Indigenous and non-Indigenous peoples into explained and unexplained components. The explained (endowment) component captures the part of the difference in a given outcome explained by differences between groups in the level of observed characteristics (determinants) that were assessed (i.e., demographic, socioeconomic and geographic variables). The unexplained (response or return) component captures the portion attributable to differences in the effects of these characteristics and unobserved determinants on the outcome of interest in non-Indigenous and Indigenous population. The absolute value of the explained component for income factor, for example, can determine how much the gap in the mean of psychological distress levels between non-Indigenous and Indigenous population would reduce if the income of Indigenous peoples is set to be at the similar level of non-Indigenous Canadian, *ceteris paribus* (1–3).

We applied the two-fold BO decomposition and assume Indigenous peoples have comparative disadvantages than non-Indigenous peoples in relation to the three mental health outcomes being assessed.¹ We considered that the psychological issues among Indigenous peoples and non-Indigenous peoples are related to vectors of demographic, socioeconomic and geographic factors for Indigenous and non-Indigenous peoples, respectively) as follows:

$$Y_{Ii} = \alpha_I + X_{Ii}\beta_I + \mu_{Ii} \quad \text{and} \quad Y_{Ni} = \alpha_N + X_{Ni}\beta_N + \mu_{Ni}. \quad (2)$$

Where α_I and α_N are intercepts. β_I and β_N are the coefficients indicating the effect of the observable characteristics on mental health outcomes, and μ_{Ii} and μ_{Ni} are error terms with zero expected value. If we take the expectations of non-Indigenous and Indigenous peoples' mental health outcomes and subtract the expected values between the two groups, we can get Equation 3.²

$$Diff = \bar{Y}_N - \bar{Y}_I = \alpha_N + \bar{X}_N\beta_N - \alpha_I - \bar{X}_I\beta_I. \quad (3)$$

Adding and subtracting the term $\bar{X}_I\beta_N$ in Equation 3 leads to:

$$Diff = (\bar{X}_N - \bar{X}_I)\beta_N + \bar{X}_I(\beta_N - \beta_I) + (\alpha_N - \alpha_I). \quad (4)$$

The first component in Equation 4, $(\bar{X}_N - \bar{X}_I)\beta_N$, is the explained component and represents the difference in the given mental health outcome between two groups that is explained by variation in the mean level of observable characteristics. The second component, $\bar{X}_I(\beta_N - \beta_I) + (\alpha_N - \alpha_I)$, indicates the unexplained component and represents the difference in the outcome of interest that is due to differences in returns to observable and unobserved characteristics on the outcome of interest between two groups.

We used the BO decomposition for a linear model to assess the differences in the mean psychological distress. The extended version of the BO technique for a non-linear logit model (3) was used to examine the difference in the prevalence of suicidal ideation and suicide plans. Past studies have highlighted certain issues related to the choice of the reference group when dummy or categorical variables used in the decomposition analysis (4–6). Specifically, the

¹ Two-fold OB decomposition assumes there is a potential disadvantage (negative discrimination) on Indigenous' psychological outcomes and there is no advantage (positive discrimination) for non-Indigenous peoples.

² We assume there is a comparative disadvantage against Indigenous peoples' psychological health, comparing to non-Indigenous peoples. Since the average levels of mental health outcome variables for Indigenous peoples are higher than their non-Indigenous counterparts, the difference in Equation 3 is negative.

1
2
3 estimated coefficients are sensitive to the choice of the base category when using a categorical
4 variable in the model; thus, the decomposition results vary by altering the base group. To
5 overcome this problem, we applied the deviation contrast transformation to each set of
6 categorical variables and restricted the coefficients for the same set of categorical variables
7 sum up to zero (normalize). The results are equal to the simple averages of the results we
8 would get from a series of decompositions in which the categories are used one after another
9 as the reference category. This approach overcomes the issue related to the choice of the
10 reference category as the contribution of a categorical predictor to the unexplained part of
11 the decomposition does not depend on the choice of the reference category.
